AB Kainate receptor glutamate receptor 6 (GluR6) subunit-deficient and c-Jun N-terminal kinase 3 (**JNK3**)-null mice share similar phenotypes including resistance to kainite-induced epileptic seizures and neuronal toxicity (Yang, D. D., Kuan, C-Y., Whitmarsh, A. J., Rincon, M., Zheng, T. S., Davis, R. J., Rakis, P., and Flavell, R. (1997) Nature 389, 865-869; Mulle, C., Seiler, A., Perez-Otano, I., Dickinson-Anson, H., Castillo, P. E., Bureau, I., Maron, C., Gage, F. H., Mann, J. R., Bettler, B., and Heinemmann, S. F. (1998) Nature 392, 601-605). This suggests that **JNK** activation may be involved in GluR6-mediated **excitotoxicity**. We provide evidence that post-synaptic density protein (PSD-95) links GluR6 to **JNK** activation by anchoring mixed lineage kinase (MLK) 2 or MLK3, upstream activators of **JNKs**, to the receptor complex. Association of MLK2 and MLK3 with PSD-95 in HN33 cells and rat brain preparations is dependent upon the SH3 domain of PSD-95, and expression of GluR6 in HN33 cells activated **JNKs** and induced neuronal apoptosis. Deletion of the PSD-95-binding site of GluR6 reduced both **JNK** activation and neuronal toxicity. Co-expression of dominant negative MLK2, MLK3, or mitogen-activated kinase kinase (MKK) 4 and MKK7 also significantly attenuated **JNK** activation and neuronal toxicity mediated by GluR6, and co-expression of PSD-95 with a deficient Src homology 3 domain also inhibited GluR6-induced **JNK** activation and neuronal toxicity. Our results suggest that PSD-95 plays a critical role in GluR6-mediated **JNK** activation and **excitotoxicity** by anchoring MLK to the receptor complex.

AB c-Jun N-terminal kinases (**JNKs**) regulate gene expression by phosphorylating transcription factors, such as c-Jun. Studies with **JNK**: knockout mice suggest that **JNK** activity may be required for **excitotoxin**-induced apoptosis in the adult hippocampus and for apoptosis in the developing embryonic neural tube. Here we investigate the role of **JNKs** in classical neurotrophin-regulated developmental neuronal death by using nerve growth factor (NGF)-dependent sympathetic neurones. In this system, NGF withdrawal leads to an increase in **JNK** activity, an increase in c-Jun protein levels and c-Jun N-terminal phosphorylation before the cell death commitment point, and c-Jun activity is required for cell death. To inhibit **JNK** activity in sympathetic neurones we have used two different **JNK** inhibitors that act by distinct mechanisms: the compound SB 203580 and the **JNK** binding domain (JBD) of **JNK** interacting protein 1 (JIP-1). We demonstrate that **JNK** activity is required for c-Jun phosphorylation, c-jun promoter activation and NGF withdrawal-induced apoptosis. We also show that ATF-2, a c-Jun dimerization partner that can regulate c-jun gene expression, is activated following NGF deprivation. Finally, by co-expressing the JBD and a regulatable c-Jun dominant negative mutant we demonstrate that **JNK** and AP-1 function in the same pro-apoptotic signalling pathway after NGF withdrawal.

AB There has been considerable interest in the molecular mechanisms of apoptosis in mammalian neurons because this form of neuronal cell death is important for the normal development of the nervous system and because inappropriate neuronal apoptosis may contribute to the pathology of human neurodegenerative disease. The aim of recent research has been to identify the key components of the cell death machinery in neurons and understand how the cell death programme is regulated by intracellular signalling pathways activated by the binding of neurotrophins or death factors to specific cell surface receptors. The aim of this commentary was to review research that has investigated the role of the Jun N-terminal kinase (**JNK**)/c-Jun signalling pathway in neuronal apoptosis, focusing in particular on work carried out with developing sympathetic neurons. Experiments with sympathetic neurons cultured in vitro, as well as with cerebellar granule neurons and differentiated PC12 cells, have demonstrated that JNK/c-Jun signalling can promote apoptosis following survival factor withdrawal. In addition, experiments with

Jnk(-/-) knockout mice have provided evidence that **Jnk3** may be required for apoptosis in the hippocampus in vivo following injection of kainic acid, an **excitotoxin**, and that Jnk1 and Jnk2 are required for apoptosis in the developing embryonic neural tube. However, in the embryonic forebrain, Jnk1 and Jnk2 have the opposite function and are necessary for the survival of developing cortical neurons. These results suggest that **JNKs** and c-Jun are important regulators of the cell death programme in the mammalian nervous system, but that their biological effects depend on the neuronal type and stage of development.

AB Methods are described for identifying compds. that inhibit **JNK** and MLK kinase activity as drugs for treating a mammal susceptible to or having a neurol. condition. Methods are also disclosed for preventing neuronal cell death and treating neurol. conditions that involve neuronal cell death, particularly neurodegenerative diseases characterized by glutamine- or kainate-mediated toxicity, e.g. Huntington's disease and Alzheimer's disease.

AB The c-Jun N-terminal kinase (**JNK**) group of MAP kinases are activated by exposure of cells to environmental stress. The role of **JNK** in the brain was examd. by targeted disruption of the gene that encodes the neuronal isoform **JNK3**. **JNK3** plays a role in stress-induced seizure activity, AP-1 transcriptional activation, and kainate-induced apoptosis of hippocampal neurons. Mice lacking the **JNK3** gene develop normally and are resistant to **excitotoxic** damage. Thus, **JNK3** is a mediator of kainate-glutamate **excitotoxicity** and a target for limiting or preventing **excitotoxic** damage. Methods of screening for mols. and compds. that decrease **JNK3** expression or activity are described. Such mols. or compds. are useful for treating disorders involving **excitotoxicity** such as seizure disorders, Alzheimer's disease, Huntington disease, Parkinson's disease, and ischemia.

AB Excitatory amino acids induce both acute membrane depolarization and latent cellular toxicity, which often leads to apoptosis in many neurological disorders. Recent studies indicate that glutamate toxicity may involve the c-Jun amino-terminal kinase (**JNK**) group of mitogen-activated protein (MAP) kinases. One member of the **JNK** family, **Jnk3**, may be required for stress-induced neuronal apoptosis, as it is selectively expressed in the nervous system. Here we report that disruption of the gene encoding **Jnk3** in mice caused the mice to be resistant to the **excitotoxic** glutamate-receptor agonist kainic acid: they showed a reduction in seizure activity and hippocampal neuron apoptosis was prevented. Although application of kainic acid imposed the same level of noxious stress, the phosphorylation of c-Jun

and the transcriptional activity of the AP-1 transcription factor complex were markedly reduced in the mutant mice. These data indicate that the observed neuroprotection is due to the extinction of a **Jnk3** -mediated signalling pathway, which is an important component in the pathogenesis of glutamate neurotoxicity.
